

DEVELOP AND TEST ON A HOST MACHINE WITHOUT TARGET HARDWARE

MapuSoft's Linux/POSIX OS Simulator allows engineers to develop and test Linux/POSIX applications on Windows or Linux host environments. Linux/POSIX OS Simulator eliminates the need for the Linux/POSIX OS as well as the requirement for expensive target hardware during development. Without the need for those components, development and testing can begin much earlier. The result is lower licensing costs, reduced hardware requirements and a shorter time to market.

Linux/POSIX OS Simulator also provides a virtualized test platform to simulate a system of applications interacting with each other on multiple CPU cores through simulated devices. Optionally, Linux/POSIX OS Simulator is available with source code to simulate Linux/POSIX applications integrated with native tools/software on Windows or Linux target environments.

USING OS SIMULATOR AS A DEVELOPMENT PLATFORM

Linux/POSIX OS Simulator is integrated with AppCOE, an Eclipse-based framework packaged with CDT, BIRT and GNU x86 tools, providing a state-of-the-art IDE for development and testing. Linux/POSIX OS Simulator provides the following features when used as a development platform:

- Allows you to simulate real-time applications on Windows or Linux hosts by hardening and optimizing the underlying OS platform
- Linux/POSIX and OS Abstractor Interfaces in non-source are provided in object format for development, simulation, testing and integration of Linux/POSIX applications on a x86 host environment
- Optionally, the Linux/POSIX and OS Abstractor Interface libraries are available in full source code format for use with target native tools/software on Windows or Linux
 - > Source code option allows for gathering profiler data regarding the application and the Interfaces so that they can be optimized

USING OS SIMULATOR AS A VIRTUALIZED TESTING PLATFORM

Linux/POSIX OS Simulator provides the ability to simulate, test and run an entire system of C/C++ Linux/POSIX applications on a Windows or Linux host. Host-based testing offers more hardware resources, less complexity and lower costs when compared to testing on a target platform. Linux/POSIX OS Simulator provides the following features when used as a virtualized testing platform:

- Ability to do modular testing
 - > Allows applications to be broken down into separate processes with dedicated heap memory and kernel resources so that individual modules can be debugged further without crashing others
 - > Can load or re-start other processes dynamically from within an application or statically load them from command prompt
 - > Simulate interacting applications with each other on one or more CPU cores using Linux/POSIX and OS Abstractor Interfaces for inter-process communication
 - > Shared tiered memory pools allow effective application-level data communication with zero copy and without having to pass through physical or virtual devices
- Easy to develop a prototype by creating low-level simulated devices using OS Abstractor APIs
