Chapter 1.About this Guide

This chapter contains the following topics:

Objectives

Audience

Document Conventions

MapuSoft Technologies and Related Documentation

Requesting Support

Documentation Feedback

Objectives

This manual contains instructions on how to get started with the Mapusoft products. The intention of the document is to guide the user to install, configure, build and execute the applications using Mapusoft products.

Audience

This manual is designed for anyone who wants to port applications to different operating systems, create projects, and run applications. This manual is intended for the following audiences:

- Customers with technical knowledge and experience with the Embedded Systems
- Application developers who want to migrate their application to different RTOSs
- Managers who want to minimize the cost and leverage on their existing code

Document Conventions

Table 1_1 defines the notice icons used in this manual.

Table 1_1: Notice Icons

Icon	Meaning	Description
☞	Informational note	Indicates important features or icons.
⚠	Caution	Indicates a situation that might result in loss of data or software damage.

Table 1_2 defines the text and syntax conventions used in this manual.

Table 1_2: Text and Syntax Conventions

Convention	Description
Courier New	`Identifies Program listings and Program examples.`
Italic text like this	`Introduces important new terms.` • `Identifies book names` • `Identifies Internet draft titles.`
COURIER NEW, ALL CAPS	`Identifies File names.`
Courier New, Bold	`Identifies Interactive Command lines`

MapuSoft Technologies and Related Documentation

Reference manuals can be provided under NDA. Click http://mapusoft.com/contact/ to request for a reference manual.

The document description table lists MapuSoft Technologies manuals.

Table 1_3: Document Description Table

User Guides	Description
	•
AppCOE Quick Start Guide	Provides detailed description on how to become familiar with AppCOE product and use it with ease. This guide: • Explains how to quickly set-up AppCOE on Windows/Linux Host and run the demos that came along AppCOE
Application Common Operating Environment Guide	Provides detailed description of how to do porting and abstraction using AppCOE. This guide: • Explains how to port applications • Explains how to import legacy applications • Explains how to do code optimization • Explains how to generate library packages • Explains on Application profiling and platform profiling
OS Abstractor Interface Reference Manual	Provides detailed description of how to use OS Abstraction. This guide: • Explains how to develop code independent of the underlying OS • Explains how to make your software easily support multiple OS platforms
POSIX Interface Reference Manual	Provides detailed description of how to get started with POSIX interface support that MapuSoft provides. This guide: • Explains how to use POSIX interface, port applications
micron-ITRON Interface Reference Manual	Provides detailed description of how to get started with micron-ITRON interface support that MapuSoft provides. This guide: • Explains how to use micron-ITRON interface, port applications
pSOS Interface Reference Manual	Provides detailed description of how to get started with pSOS interface support that MapuSoft provides. This guide: • Explains how to use pSOS interface, port applications
pSOS Classic Interface Reference Manual	Provides detailed description of how to get started with pSOS Classic interface support that MapuSoft provides. This guide • Explains how to use pSOS Classic interface, port applications
Nucleus Interface Reference Manual	Provides detailed description of how to get started with Nucleus interface support that MapuSoft provides. This guide:

	• Explains how to use Nucleus interface, port applications
ThreadX Interface Reference Manual	Provides detailed description of how to get started with ThreadX interface support that MapuSoft provides. This guide: Explains how to use ThreadX interface, port applications
VxWorks Interface Reference Manual	Provides detailed description of how to get started with VxWorks Interface support that MapuSoft provides. This guide: Explains how to use VxWorks Interface, port applications
µC/OS Interface Reference Manual	Provides detailed description of how to get started with µC/OS interface support that MapuSoft provides. This guide: Explains how to use µC/OS interface, port applications
FreeRTOS Interface Reference Manual	Provides detailed description of how to get started with FreeRTOS interface support that MapuSoft provides. This guide: Explains how to use FreeRTOS interface, port applications
RTLinux Interface Reference Manual	Provides detailed description of how to get started with RTLinux interface support that MapuSoft provides. This guide: Explains how to use RTLinux interface, port applications
VRTX Interface Reference Manual	Provides detailed description of how to get started with VRTX interface support that MapuSoft provides. This guide: Explains how to use VRTX interface, port applications
QNX Interface Reference Manual	Provides detailed description of how to get started with QNX interface support that MapuSoft provides. This guide: Explains how to use QNX interface, port applications
Windows Interface Reference Manual	Provides detailed description of how to get started with Windows interface support that MapuSoft provides. This guide: • Explains how to use Windows interface, port applications
Release Notes	Provides the updated release information about MapuSoft Technologies new products and features for the latest release. This document: • Gives detailed information of the new products • Gives detailed information of the new features added into this release and their limitations, if required

Requesting Support

Technical support is available through the MapuSoft Technologies Support Centre. If you are a customer with an active MapuSoft support contract, or covered under warranty, and need post sales technical support, you can access our tools and resources online or open a conversation/ticket at http://www.mapusoft.com/support

Anyone can initially contact sales/admin/tech via the above mechanism, however tech support is offered to only registered users or evaluation customers.

Registering a New Account

If you are a customer with valid tech support contract or a trial user, please request a account be created by providing your email address, company address, telephone number etc by contacting sales@mapusoft.com. You will be provided via account name (your email) and also password to sign-in

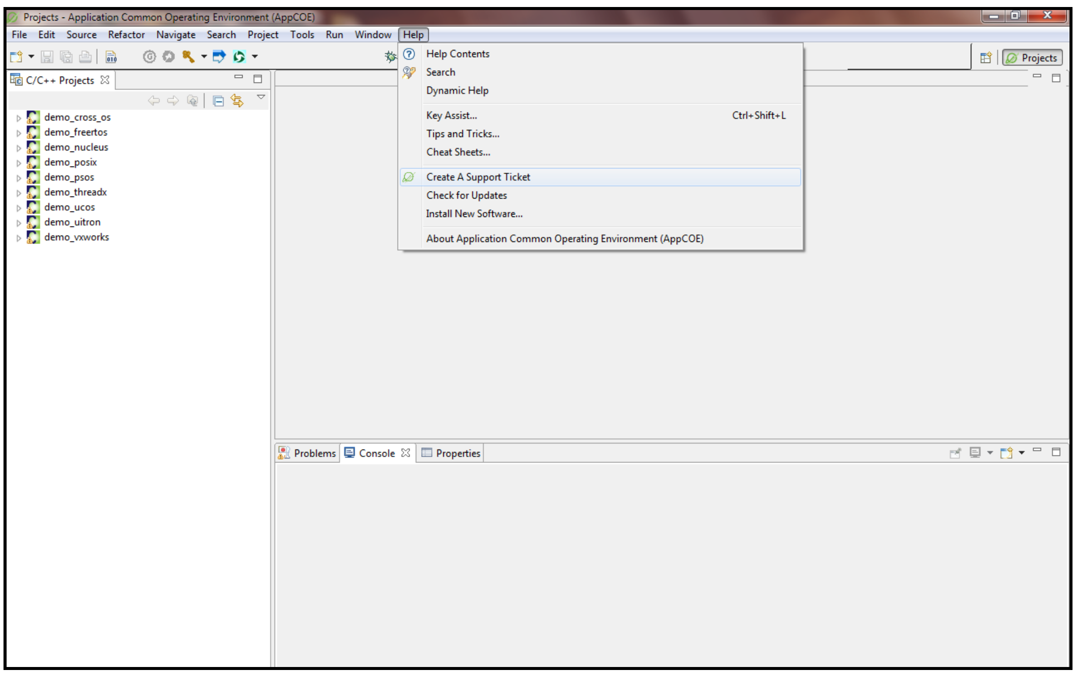
Submitting a Ticket

1. To submit a ticket, simple sign-in into your account http://www.mapusoft.com/support and open a conversation.

2. To submit a ticket from within AppCOE IDE

From AppCOE main menu, Select Help > Create a Support Ticket as shown in below Figure

Figure: Create a Support Ticket from AppCOE



To submit a ticket, simple sign-in into your account http://www.mapusoft.com/support and open a conversation.

MapuSoft Support personnel will get back to you within 48 hours with a valid response.

Live Support

Chat: MapuSoft Technologies also provides technical support through Live Chat from www.mapusoft.com website. If Chat is offline, please leave a detailed message including your email address, telephone number and company name so that MapuSoft personnel's can quickly respond to either responding to your chat by calling you on the number that you have provided

Telephone: You can also reach us at our toll free number: **1-877-627-8763** and press the tech support option to contact MapuSoft tech support team for any urgent assistance.

Documentation Feedback

We greatly appreciate your feedback. Simple sign-in or just start a conversation and let us know via: http://www.mapusoft.com/support

Chapter 2. System Configuration

This chapter contains the information about the System Configuration with the following topics:

- System Configuration
- Target OS Selection
- OS HOST Selection
- Target 64 bit CPU Selection
- User Configuration File Location
- OS Changer Components Selection
- POSIX Interface Selection
- OS Abstractor Interface Process Feature Selection
- OS Abstractor Interface Task-Pooling Feature Selection
- OS Abstractor Interface Profiler Feature Selection
- OS Abstractor Interface Output Device Selection
- OS Abstractor Interface Debug and Error Checking
- OS Abstractor Interface ANSI API Mapping
- OS Abstractor Interface Resource Configuration
- OS Abstractor Interface Minimum Memory Pool Block Configuration
- OS Abstractor Interface Application Shared Memory Configuration
- OS Abstractor Interface Clock Tick Configuration
- OS Abstractor Interface Device I/O Configuration
- OS Abstractor Interface Target OS Specific Notes
- Runtime Memory Allocations
- OS Abstractor Process Feature
- Simple (single-process) Versus Complex (multiple-process) Applications

System Configuration

The user configuration is done by setting up the appropriate value to the pre-processor defines found in the cross_os_usr.h.

NOTE: Make sure the OS Abstractor Interface libraries are re-compiled and newly built whenever configuration changes are made to the os_target_usr.h when you build your application. In order to re-build the library, you would actually require the full-source code product version (not the evaluation version) of OS Abstractor Interface.

Applications can use a different output device as standard output by modifying the appropriate functions defines in os_target_usr.h along with modifying os_setup_serial_port.c module if they choose to use the format Input/output calls provided by the OS AbstractorInterface.

Target OS Selection

Based on the OS you want the application to be built, set the pre-processor definition in your project setting or make files by using the Table 2_1.

Table 2_1: Set the Pre-processor Definition For Selected Target OS

Flag and Purpose	Available Options
OS_TARGET To select the target operating system.	The value of the OS_Target should be for the OS Abstractor Interface product that you have purchased. For Example, if you have purchased the license for : **OS_NUCLEUS** – Nucleus PLUS® from ATI **OS_THREADX** – ThreadX® from Express Logic **OS_VXWORKS** – VxWorks® from Wind River Systems **OS_ECOS** – eCOS standards from Red Hat **OS_MQX** - Precise/MQX® from ARC International **OS_UITRON** – micro-ITRON standard based OS **OS_LINUX** - Open-source/commercial Linux® distributions **OS_WINDOWS** – Windows 2000, Windows XP®, Windows CE, Windows Vista from Microsoft. If you need to use the OS Abstractor Interface both under Windows and Windows CE platforms, then you will need to purchase additional target license. **OS_TKERNEL** – Japanese T-Kernel® standards based OS **OS_LYNXOS** - LynxOS® from LynuxWorks **OS_QNX** – QNX operating system from QNX **OS_LYNXOS** – LynxOS from Lynuxworks **OS_SOLARIS** – Solaris from SUN Microsystems **OS_ANDROID** – Mobile Operating System running on Linux Kernel **OS_NETBSD** – UNIX like Operating System **OS_UCOS** – µCOS from Micrium **OS_FREERTOS –** FreeRTOS from Real Time Engineers Ltd For example, if you want to develop for ThreadX, you will define this flag as follows: OS_TARGET = OS_THREADX PROPRIETARY OS: If you are doing your own porting of OS Abstractor Interface to your proprietary OS, you could add your own define for your OS and include the appropriate OS interface files within os_target.h file. MapuSoft can also add custom support and validate the OS Abstraction solution for your proprietary OS platform

OS HOST Selection

The flag has to be false for standalone generation.

Table 2_2: Select the host operating system

Flag and Purpose	Available Options
OS_HOST To select the host operating system	This flag is used only in AppCOE environment. It is not used in the target environment. In Standalone products, this flag should be set to OS _FALSE.

Target 64 bit CPU Selection

Based on the OS you want the application to be built, set the following pre-processor definition in your project setting or make files:

Table 2_3: Select the Target CPU type

Flag and Purpose	Available Options
OS_CPU_64BIT To select the target CPU type.	The value of OS_CPU_64BIT can be any ONE of the following: • OS_TRUE – Target CPU is 64 bit type CPU • OS_FALSE – Target CPU is 32 bit type CPU **NOTE**: This value cannot be set in the cross_os_usr.h, instead it needs to be passed to compiler as –D macro either in command line for the compiler or set this pre-processor flag via the project settings. If this macro is not used, then the default value used will be OS_FALSE.

Select the OS Changer components for your application use as follows:

Table 2_4: OS Changer components for your application

Compilation Flag	Meaning
MAP_OS_ANSI_FMT_IO	Maps ANSI Formatted I/O functions to the OS Abstractor equivalent
MAP_OS_ANSI_IO	Maps ANSI I/O functions to the OS Abstractor equivalent
INCLUDE_OS_PSOS_CLASSIC	set to OS_TRUE to build for use with the OS Changer for pSOS Classic product

Select the following definition if you want OS Changer to enable error checking for debugging purposes:

Table 2_5: Set the Pre-processor Definition For error checking

Compilation Flag	Meaning
OS_DEBUG_INFO	Enable error checking for debugging

User Configuration File Location

The default directory location of the cross_os_usr.h configuration file is given below:

Table 2_6: Cross_os_usr.h Configuration File

Target OS	Configuration Files Directory Location
OS_NUCLEUS	\mapusoft\cros_os_nucleus\include
OS_THREADX	\mapusoft\cross_os_threadx\include
OS_VXWORKS	\mapusoft\cross_os_vxworks\include Please make sure you specify the appropriate target OS versions that you use in the osabstractor_usr.h
OS_MQX	\mapusoft\cross_os_mqx\include
OS_UITRON	\mapusoft\cross_os_uitron\include
OS_LINUX	\mapusoft\cross_os_linux\include Please make sure you specify the appropriate target OS versions that you use in the cross_os_usr.h **NOTE**: RT Linux, for using RT Linux you need to select this option.
OS_SOLARIS	\mapusoft\cross_os_solaris\include
OS_WINDOWS	\mapusoft\cross_os_windows\include Any windows platform including Windows CE platform. If you use OS Abstractor Interfaceunder both Windows and Windows CE, then you would require additional target license. **NOTE**: Windows 2000, Windows XP®, Windows CE, Windows Vista from Microsoft
OS_ECOS	\mapusoft\cross_os_ecos\include
OS_LYNXOS	\mapusoft\cross_os_lynxos\include
OS_QNX	\mapusoft\cross_os_qnx\include
OS_TKERNEL	\mapusoft\cross_os_tkernel\include
OS_ANDROID	\mapusoft\cross_os_android\include
OS_NETBSD	\mapusoft\cross_os_netbsd\include
OS_UCOS	\mapusoft\cross_os_ucos\include
OS_FREERTOS	\mapusoft\cross_os_freertos\include
OS_RTLINUX	\mapusoft\cross_os_rtlinux\include
OS_VRTX	\mapusoft\cross_os_vrtx\include
OS_QNX	\mapusoft\cross_os_qnx\include

If you have installed the MapuSoft's products in directory location other than mapusoft then refer the corresponding directory instead of \mapusoft for correct directory location.

OS Changer Components Selection

OS Abstractor optional comes with various OS Changer API solutions in addition to its BASE and POSIX API offerings. OS Changer APIs are used to port legacy code base from one OS to another. Select one or more OS Changer components depending on the type of code that you needed to port to one or more new operating system platforms. Set the pre-processor flag below to select the components needed by your application:

Table 2_7: OS Changer Components Selection

Flag and Purpose	Available Options
INCLUDE_OS_VXWORKS To include VxWorks Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_POSIX/LINUX To include POSIX/LINUX Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_PSOS To include pSOS Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_PSOS_CLASSIC To include a very old version of pSOS Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support for pSOS 4.1 rev 3/10/1986 OS_FALSE – do not include pSOS 4.1 support The default is OS_FALSE
INCLUDE_OS_UITRON To include UITRON Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_NUCLEUS To include Nucleus PLUS Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE.
INCLUDE_OS_NUCLEUS_NET To include Nucleus NET Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE.
INCLUDE_OS_THREADX To include ThreadX Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_UCOS To include µC/OS Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_FREERTOS To include FreeRTOS Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_RTLINUX To include RTLinux Interface product. Refer to the appropriate	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE

Interface manual for more details.	
INCLUDE_OS_VRTX To include VRTX Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_QNX To include QNX Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE
INCLUDE_OS_FILE To include ANSI file system API compliance for the vendor provided File Systems. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE. This option is only available for Nucleus PLUS target OS
INCLUDE_OS_WINDOWS To include Windows Interface product. Refer to the appropriate Interface manual for more details.	OS_TRUE – Include support OS_FALSE – Do not include support The default is OS_FALSE This option is not available on Windows operating system host or target environment

NOTE: For additional information regarding how to use any specific Interface product, refer to the appropriate reference manual or contact www.mapusoft.com.

POSIX OS Abstractor Selection

OS Abstractor Interface optionally comes with POSIX support as well. Set the pre-processor flag provided below to select the POSIX component for application use as follows:

Table 2_8: POSIX component for application

Flag and Purpose	Available Options
INCLUDE_OS_POSIX To include POSIX Interface product component.	**OS_TRUE** – Include support. You will need this option turned ON either if the underlying OS does not support POSIX (or) you need to POSIX provided by OS Abstractor Interface instead of the POSIX provided natively by the target OS OS_FALSE – Do not include support The default is OS_FALSE.

NOTE: The above component can be used across POSIX based and non-POSIX based target OS for gaining full portability along with advanced real-time features. POSIX Interface library will provide the POSIX functionality instead of application using POSIX functionalities directly from the native POSIX from the OS and as a result this will ensure that your application code will work across various POSIX/UNIX based target OS and also its various versions while providing various real-time API and performance features. In addition, OS Abstractor Interface will allow the POSIX application to take advantage of safety critical features like task-pooling, fixing boundary for application's heap memory use, self recovery from fatal errors, etc. (these features are defined elsewhere in this document). For added flexibility, POSIX applications can also take advantage of using OS Abstractor Interface APIs non-intrusively for additional flexibility and features.

OS Abstractor Process Feature Selection

Table 2_9: OS Abstractor Process Feature Selection

Flag and Purpose	Available Options
INCLUDE_OS_PROCESS	OS_TRUE – Include OS Abstractor process support APIs and track resources under each process and also allow multiple individually executable applications to use OS Abstractor OS_FALSE – Do not include process model support. Use this option for optimized OS Abstractor performance The default is OS_FALSE

The INCLUDE_OS_PROCESS option is useful when there are multiple developers writing components of the applications that are modular. The resource created by the process is automatically tracked and when the process goes away they also go away. One process can use another process resource, only if that process is created with "system" scope. A process cannot delete a resource that it did not create.

The INCLUDE_OS_PROCESS feature can also be used on target OS like VxWorks 5.x a non-process based operating system. In this case, the OS Abstractor provides software process protection. Under process-based OS like Linux, the processes created by the OS Abstractor will be an actual native system processes.

The INCLUDE_OS_PROCESS feature is also useful to simulate complex multiple embedded controller application on x86 single processor host platform. In this case, each individual process /application will represent individual controllers, which uses a shared memory region for inter-communication. This application could then be ported to the real multiple embedded controller environments with shared physical memory.

Process Feature use within OS Changer

It is possible for legacy applications to use the process feature along with OS Changer and take advantage of process protection mechanism and also have the ability to break down the complex application into multiple manageable modules to reduce complexity in code development. However, when porting legacy code, we recommend that the application be first ported to a single process successfully. Once this is completed, then the application can be modified to move the global data to shared memory and can be made to easily reside into individual process and or multiple executables.

To allow the legacy applications to be broken down into process modules and /or multiple applications the flag INCLUDE_OS_PROCESS needs to be set to OS_TRUE. Also the application needs to use OS_Create_Process envelopes to move the resources to appropriate processes. Legacy application can also make in multiple applications which then compile separately and can continue to use Interface APIs for inter-process communication. Interface APIs provides transparency to the application and allows the application to use the API among resources within a single process or multiple processes /applications.

OS Abstractor Task-Pooling Feature Selection

Task-Pooling feature enhances the performances and reliability of application. Creating a task (thread) at run-time require considerable system overhead and memory. The underlying OS thread creation function call can take considerable amount of time to complete the operation and could fail if there is not enough system memory. Enabling this feature, Applications can create OS Abstractor tasks during initialization and be able to re-use the task envelope again and again. To configure task-pooling, set the following pre-processor flag as follows:

Table 2_10: OS Abstractor Task-Pooling Feature Selection

Flag and Purpose	Available options
INCLUDE_OS_TASK_POOLING	OS_TRUE – Include OS Abstractor task pooling feature to allow applications to re-use task envelops from task pool created during initialization to eliminate run-time overhead with actual resource creation and deletion OS_FALSE – Do not include task pooling support The default is OS_FALSE Note: This setting can be overridden only to disable during **OS_Application_Init** call by using 'task_pool_enabled' flag of OS_APP_INIT_INFO structure. This setting is common to all created process under one application.

Except for the performance improvement, this behavior will be transparent to the application. Each process /application will contain its own individual task pool. Any process, which requires a task pool, must successfully add tasks to the pool before it can be used. Tasks can be added to (via OS_Add_To_Task_Pool function) or removed (via OS_Remove_From_Task_Pool function) from a task pool at anytime.

When an application makes a request to use a pool task, OS Abstractor will first search for a free task in the pool with an exact match based on stack size. If it does not find a match, then a free task with the next larger stack size that is available will be used. If there are multiple requests pending, a search will be made in FIFO order on the request list when a task is freed to the pool. The first request that matches or fulfills the stack requirement will then be fulfilled.

Refer to the MapuSoft supplied os_application_start.c file that came with the MapuSoft's demo application. The demo application pre-creates a bunch of fixed-stack-size (using STACK_SIZE as defined in cross_os_def.h) task-pool-task as shown below:

```
#if (INCLUDE_OS_TASK_POOLING == OS_TRUE)
      for(i = 0; i < Max_Threads; i++)
      {
      OS_Add_To_Task_Pool(STACK_SIZE); /*this is a portion of code in
      init.c,
                                         STACK_SIZE should be changed
                                         according to the desired stack size
```

```
    }
#endif
```

Typically, applications would need a variety of threads with different stack size. If you would like to modify the demo application to use threads with larger or differing stack size, make sure you modify the `os_application_start.c` file according to your needs.

The OS_Create_Task function will be used to retrieve a task from the task pool. This will be accomplished by passing one of the flags OS_POOLED_TASK_WAIT or `OS_POOLED_TASK_NOWAIT` as a parameter to `OS_Create_Task`. When a task has completed and either exits, falls through itself or gets deleted by another task using the `OS_Delete_Task` function, the task will automatically be freed to be used again by the task pool. For further details, please refer to the `OS_Create_Task` specification defined in the following pages.

An Application can add or remove tasks with a specified stack size to the task pool at any time. The task pool will grow or shrink depending on each addition or deletion of tasks in the task pool. The Application cannot remove a valid task, which does not belong to the task pool. `OS_Get_System_Info` function can be used to retrieve the system configuration and run-time system status including information related to task pool.

If `OS_TASK_POOLING` is enabled, then all tasks POSIX threads created using the POSIX Interface POSIX APIs provided by POSIX Interface with POSIX and/or any task creation created using task create functions in any Interface products will automatically use the task pool mechanism with the flag option set to `OS_POOLED_TASK_NOWAIT`.

Warning: Your application will fail during task creation if OS_TASK_POOLING is enabled and you have not added any tasks to the task pool. Make sure you add tasks (via `OS_Add_To_Task_Pool` function) with all required stack sizes prior to creating pooled tasks (via OS_Create_Task function).

Special Notes: Task Pooling feature is not supported in ThreadX, µCOS, Nucleus, and FreeRTOS targets.

OS Abstractor Profiler Feature Selection

The following are the user configuration options that can be set in the cross_os_usr.h:

Table 2_11: OS Abstractor Profiler Feature Selection

Flag and Purpose	Available Options
OS_PROFILER Profiler feature allows applications running on the target to collect valuable performance data regarding the application's usage of the OS Abstractor APIs. Using the AppCOE tool, this data can then be loaded and analyzed in graphical format. You can find out how often a specific OS Abstractor API is called across the system or within a specific thread. You can also find out how much time the functions took across the whole system as well as within a specific thread Profiler feature uses high resolution clock counters to collect profiling data and this implementation may not be available for all target CPU and OS platforms. Please contact MapuSoft for any custom high resolution timer implementation required for the profiler for your target/OS environment. Refer to `OS_Get_Hr_Clock_Freq()` and `OS_Read_Hr_Clock()` for additional details on what target/OS platforms are currently supported by the profiler. If profiler feature is turned ON, then it needs to use the open/read/write calls to write to profiler data file. Make sure OS_MAP_ANSI_IO to OS_FALSE which is no longer supported.	Can either be: **OS_FALSE** – Profiler code will be excluded and the feature will be turned off. No APIs profiled. The default value is OS_FALSE**.** **OS_TRUE** – Profiler feature will be included. Profiling takes place with each OS Abstractor API call. If profiler is turned on, also set the value for the following defines: *PROFILER_TASK_PRIORITY* The priority level (0 to 255) of the profiler thread. The profiler thread starts picking up the messages in the profiler queue, formats them into XML record and write to file. If the priority is set to the lowest (i.e, 255), then the profiler thread may not have an opportunity to pick the message from the queue in time and as such the queue gets filled up and as such the profiler will stop. The default profiler task priority value is set to 200. *NUM_OF_MSG_TO_HOLD_IN_MEMORY* This will be the depth of the profiler queue. The bigger the number, the more the memory is needed. Please make sure you increase you application's heap size by NUM_OF_MSG_TO_HOLD_IN_MEMORY times PROFILER_MSG_SIZE in the OS_Application_Init call**.** See special notes1 below for an example of how you change this value. *NUM_OF_PROFILER_MSG* This will be …. By default, this is set a max of 30,000 data record. See special notes1 below for an example of how you change this value *PROFILER_DATAFILE_PATH* This will be the directory location where the profiler file will be created. For Linux, the default location set is "/root".

	OS_ENABLE_BASE_PROFILING (OS Abstractor) *OS_ENABLE_POSIX_PROFILING* *OS_ENABLE_UITRON_PROFILING* *OS_ENABLE_VXWORKS_PROFILING* *OS_ENABLE_PSOS_PROFILING* *OS_ENABLE_NUCLEUS_PROFILING* *OS_ENABLE_THREADX_PROFILING* *OS_ENABLE_FREERTOS_PROFILING* *OS_ENABLE_UCOS_PROFILING* *OS_ENABLE_VRTX_PROFILING* *OS_ENABLE_QNX_PROFILING* *OS_ENABLE_RTLINUX_PROFILING* *OS_ENABLE_WINDOWS_PROFILING* Set the above defines to OS_TRUE to enable profiling selectively required API Interfaces. The default value is OS_FALSE for all above**.**

The profiler starts as soon as the application starts and will continue to collect performance data until the memory buffers in the profiler queue gets filled up. After, this the profiling stops and data is dumped into *.pal files at the user specified location. It is recommended that the profiler feature be turned off for the production release of your application.

If the profiler feature is turned OFF, then the profiler hooks disappear within the OS Abstractor and as such there are no impacts to the OS Abstractor API performance.

Special Notes 1: Here is an example on how to change NUM_OF_MSG_TO_HOLD_IN_MEMORY & NUM_OF_PROFILER_MSG from their default value of 1000 and 30,000 to 500 and 5000 respectively.

```
/* Number of profiler messages to be collected in memory */
#define NUM_OF_MSG_TO_HOLD_IN_MEMORY 500

#define NUM_OF_PROFILER_MSG       (NUM_OF_MSG_TO_HOLD_IN_MEMORY < 5000 ) ?
(NUM_OF_MSG_TO_HOLD_IN_MEMORY + 10) : 5000
```

Special Notes 2: Profiler feature is not supported in ThreadX and Nucleus targets.

OS Abstractor Output Device Selection

The following are the user configuration options and their meanings:

Table 2_12: OS Abstractor Output Device Selection

Flag and Purpose	Available options
OS_STD_OUTPUT	Output device to print. OS_SERIAL_OUT – Print to serial OS_WIN_CONSOLE – Print to console User can print to other devices by modifying the appropriate functions within os_setup_serial_port.c in the OS Abstractor "source" directory and use OS Abstractor's format Input/Output calls. The default value is OS_WIN_CONSOLE

OS Abstractor Debug and Error Checking

Table 2_13: OS Abstractor Debug and Error Checking

Flag and Purpose	Available Options
OS_DEBUG_INFO	**OS_DEBUG_MINIMAL** – print debug info, fatal and compliance errors **OS_DEBUG_VERBOSE** –print the debug information, Fatal Error & Compilation Error elaborately. **OS_DEBUG_DISABLE** -do not print debug info The default value is **OS_DEBUG_MINIMAL**
OS_ERROR_CHECKING	OS_TRUE – Check for API usage errors OS_FALSE – do not check for errors. Use this option to increase performance and reduce code size. The default value is OS_TRUE

OS Abstractor ANSI API Mapping

OS Abstractor APIs can be mapped to exact ANSI names by turning on these features:

Table 2_14: OS Abstractor ANSI API Mapping

Flag and Purpose	Available options
MAP_OS_ANSI_MEMORY	**NOTE**: This feature is NO LONGER supported.
MAP_OS_ANSI_FMT_IO	**OS_FALSE** – do not map functions. Make sure this as default because this feature is no longer supported. The default value is OS_FALSE

MAP_OS_ANSI_IO	**OS_FALSE** – do not map functions. Make sure this as default because this feature is no longer supported. The default value is OS_FALSE

NOTE: Make sure **OS_FALSE** as default because this feature is no longer supported.

OS Abstractor External Memory Allocation

OS Abstractor APIs can be mapped to exact ANSI names by turning on these features:

Table 2_15: OS Abstractor External Memory Allocation

Flag and Purpose	Available options
OS_USE_EXTERNAL_MALLOC	OS_TRUE – OS Abstractor can be configured to use an application defined external functions to allocate and free memory needed dynamically by the process. In this case, the OS Abstractor will use these function for allocating and freeing memory within `OS_Allocate_Memory` and `OS_Deallocate_Memory` functions These external functions needs to be similar to `malloc()` and free() and should be defined within cross_os_usr.h in order for OS Abstractor to successfully use them. This feature is useful if the application has its own memory management schemes far better than what the OS has to offer for dynamic allocations. OS_FALSE – OS Abstractor will directly use the target OS system calls for allocating and freeing the memory The default value is OS_FALSE

OS Abstractor Resource Configuration

In addition to OS Abstractor resources used by application, there may be some additional resources required internally by OS Abstractor. The configuration should take into the account of these additional resources while configuring the system requirements. All or any of the configuration parameters set in cross_os_usr.h configuration file can be altered by OS_Application_Init function .

The following are the OS Abstractor system resource configuration parameters:

Table 2_16: OS Abstractor system resource configuration parameters

Flag and Purpose	Default Setting
OS_TOTAL_SYSTEM_PROCESSES The total number of processes required by the application	100 One control block will be used by the OS_Application_Init function when the INCLUDE_OS_PROCESS option is true
OS_TOTAL_SYSTEM_TASKS The total number of tasks required by the application	100 One control block will be used by the OS_Application_Init function when the INCLUDE_OS_PROCESS option is true.
OS_TOTAL_SYSTEM_PIPES The total number of pipes for message passing required by the application	100
OS_TOTAL_SYSTEM_QUEUES The total number of queues for message passing required by the application	100
OS_TOTAL_SYSTEM_MUTEXES The total number of mutex semaphores required by the application	100
OS_TOTAL_SYSTEM_SEMAPHORES The total number of regular (binary/count) semaphores required by the application	100
OS_TOTAL_SYSTEM_DM_POOLS The total number of dynamic variable memory pools required by the application	100 One control block will be used by the OS_Application_Init function when the INCLUDE_OS_PROCESS option is true.
OS_TOTAL_SYSTEM_PM_POOLS The total number of partitioned (fixed-size) memory pools required by the application	100
OS_TOTAL_SYSTEM_TM_POOLS The total number of Tiered memory pools required by the application	100
OS_TOTAL_SYSTEM_TSM_POOLS The total number of Tiered shared memory pools required by the application	100

OS_TOTAL_SYSTEM_EV_GROUPS The total number of event groups required by the application	100
OS_TOTAL_SYSTEM_TIMERS The total number of application timers required by the application	100
OS_TOTAL_SYSTEM_HANDLES The total number of system Handles required by the application	100

NOTE: The first control block of Task, Queue, Dynamic Memory and Semaphore is reserved for internal use in the OS Abstractor Interface.

The following are the additional resources required internally by OS Abstractor:

Table 2_17: Additional resources required internally by OS Abstractor

Resources	Linux /POSIX ,Vxworks, pSOS ,Windows, µCOS, QNX, MQX, ThreadX, Nucleus, uITRON, NetBSD, Solaris, LynxOS, Android Targets
TASK	• 2 Semaphore required if application uses µitron Interface for above mentioned target • 1 Event Group required by OS Abstractor for signaling support in posix for above mentioned target • 1 Event group required if application uses POSIX Interface and/or VxWorks Interface and/or pSOS Interface for above mentioned target • 1 Event Group required by OS Abstractor if application uses task pooling for above mentioned target
DYNAMIC_POOL	• 1 Event Group required by OS Abstractor for above mentioned target but not for MQX Target
QUEUE	• 2 Semaphores used by OS Abstractor for above mentioned target • 1 Semaphore used by POSIX Interface for above mentioned target • Additional Queues required by OS Abstractor if application uses profiler for above mentioned target
PIPE	• 1 Additional Semaphore required by OS Abstractor
MUTEX	• Additional Protection Structure required by OS Abstractor for above mentioned target
PROCESS	• 1 DM_POOL used by OS Abstractor for above mentioned target • 1 Event Group required by OS Abstractor for above mentioned target • 1 Additional Task required by OS Abstractor for above mentioned target • 2 Protection Structures required by OS Abstractor for above mentioned target **Note:** Every process needs a memory pool only for µCOS Target
NON_PROCESS	• 1 Event Group required by OS Abstractor for Linux, Windows, MQX Target • 2 Event Group required by OS Abstractor µCOS Target
PARTITION_POOL	• 1 Semaphore is used by OS Abstractor for above mentioned target
PROTECTION_STRUCTURE	• 1 Protection Structures required by os_key_list_protect if application uses POSIX Interface for above mentioned target • 14 Additional Protection Structure required by OS Abstractor for above mentioned Targets except LynxOS Target, Vxworks & QNX Target • 13 Additional Protection Structure required by OS Abstractor for LynxOS Target, Vxworks &QNX Target

Posix Condition Variable	1 Event Group required by POSIX Interface for above mentioned target
Posix R/W Lock	1 Event Group required by POSIX Interface for above mentioned target 1 Semaphore required by POSIX Interface for above mentioned target
TIERED POOL	The size of (OS_TOTAL_SYSTEM_TM_POOLS * OS_MAX_TIER_POOL_LEVELS) partition pools are required for each Tiered Memory Pool creation.
TIERED SHARED POOL	The size of (OS_TOTAL_SYSTEM_TSM_POOLS * OS_MAX_TIER_POOL_LEVELS) semaphores are required for each Tiered Shared Memory Pool creation.

If INCLUDE_OS_PROCESS feature is set to OS_FALSE, then the memory will be allocated from the individual application/process specific pool, which gets created during the OS_Application_Init function call.

If INCLUDE_OS_PROCESS is set to OS_TRUE, then the memory is allocated from a shared memory region to allow applications to communicate across multiple processes. Please note that in this case, the control block allocations cannot be done from the process specific dedicated memory pool since the control blocks are required to be shared across multiple applications.

OS Abstractor Minimum Memory Pool Block Configuration

Table 2_18: OS Abstractor Minimum Memory Pool Block Configuration

Flag and Purpose	Default Setting
OS_MIN_MEM_FROM_POOL Minimum memory allocated by the malloc() and/or OS_Allocate_Memory() calls. This will be the memory allocated even when application requests a smaller memory size	4 (bytes) **NOTE**: Increasing this value further reduces memory fragmentation at the cost of more wasted memory.

OS Abstractor Application Shared Memory Configuration

Table 2_19: OS Abstractor Application Shared Memory Configuration

Flag and Purpose	Default Setting
OS_USER_SHARED_REGION1_SIZE Application defined shared memory region usable across all process-based OS Abstractor processes/applications. Process-based applications are required to be built with OS_INCLUDE_PROCESS feature set to OS_TRUE	1024 (bytes)

OS Abstractor includes this shared user region in the memory area immediately following all the OS Abstractor control block allocations. Applications can access the shared memory via the `System_Config->user_shared_regio`n1 global variable. Also, access to shared memory region must be protected (i.e. use mutex locks prior to read/write by the application).

NOTE: The actual virtual address of the shared memory may be different across processes/application; however the OS Abstractor initialized the `System_Config` pointer correctly during OS_Application_Init function call. Applications should not pass the shared memory region address pointer from one process to another since the virtual address pointing to the shared region may differ from process to process (instead use the above global variable defined above for shared memory region access from each process/applications).

OS Abstractor Clock Tick Configuration

Table 2_20: OS Abstractor Clock Tick Configuration

Flag and Purpose	Default Setting
OS_TIME_RESOLUTION This will be the system clock ticks (not hardware clock tick). For example, when you call OS_Task_Sleep(5), you are suspending task for a period (5* OS_TIME_RESOLUTION). See **NOTES** in this table.	10000 µ second (= 10milli sec) Normally this value is derived from the target OS. If you cannot derive the value then refer to the target OS reference manual and set the correct per clock tick value
OS_DEFAULT_TSLICE Default time slice scheduling window width among same priority pre-emptable threads when they are all in ready state.	10 Number of system ticks. If system tick is 10ms, then the threads will be schedule round-robin at the rate of every 100ms. **NOTE**: On Linux operating system, the time slice cannot be modified per thread. OS Abstractor ignores this setting and only uses the system default time slice configured for the Linux kernel. **NOTE**: Time slice option is NOT supported under micro-ITRON and FreeRTOS. **NOTE**: If the time slice value is non-zero, then under Linux the threads will use Round-Robin scheduling using the system default time slice value of Linux. If the Linux kernel support LINUX_ADV_REALTIME then the time slice value will be set accordingly.

NOTE: Since the system clock tick resolution may vary across different OS under different target. It is recommended that the application use the macro `OS_TIME_TICK_PER_SEC` to derive the timing requirement instead of using the raw system tick value in order to keep the application portable across multiple OS.

OS Abstractor Device I/O Configuration

Table 2_21: OS Abstractor Device I/O Configuration

Flag and Purpose	Default Setting
NUM_DRIVERS Maximum number of drivers allowed in the OS Abstractor driver table structure	20 **NOTE**: This excludes the native drivers the system, since they do not use the OS Abstractor driver table structure.
NUM_FILES Maximum number of files that can be opened simultaneously using the OS Abstractor file control block structure.	30 **NOTE**: One control block is used when an OS Abstractor driver is opened. These settings do not impact the OS setting for max number of files.
EMAXPATH Maximum length of the directory path name including the file name for OS Abstractor use excluding the null char termination	255 **NOTE**: This setting does not impact the OS setting for the max path/file name.
MAX_FILENAME_LENGTH	(EMAXPATH + 1) /* max chars in filename + EOS*/

OS Abstractor Acquire Resource Protection Configuration

Table 2_22: OS Abstractor's Resource Protection across tasks & SMP CPUs

Flag and Purpose	Default Setting
OS_PROTECTION_USE_MUTEX_LOCK Application defined OS_PROTECTION_USE_MUTEX_LOCK flag, it gives better performance protection than spin lock protection, it should be used only system having one or two CPU cores Note: Option to use spin_lock/mutex_lock for acquire protection is configured in NetBSD, Solaris, LynxOS, Linux & QNX RTOS.	**TRUE** This mutex lock protection saves lots of CPU time and also gives the better performance. **FALSE** If you have more than two core cores , you should use this spin lock mechanism By default settings , acquire protection using spin-lock mechanism

SMP Flags Configuration

The following is the compilation defines that can be set when building the OS Abstractor library for SMP kernel target OS:

Table 2_23: Compilation Flag for SMP

Compilation Flag	Meaning
OS_BUILD_FOR_SMP Support for Symmetric Multi-Processors **(SMP)**	Specify the SMP or non-SMP kernel. The value can be: **OS_TRUE** SMP enabled **OS_FALSE** SMP disabled

Warning: If you fail to set SMP flag to OS_TRUE (except when "OS_TARGET = OS_LINUX" and in this situation the above flag is ignored and SMP feature is automatically detected and OS Abstractor configures itself accordingly) and use Mapusoft products on an SMP enabled machine, you will get the result in an unpredictable behavior due to failure of internal data protection mechanism.

Now MapuSoft provides SMP support to the following OS's:

- Linux
- Windows XP/Vista/Mobile/CE/7
- VxWorks

Note: In case of linux target, additionally **Resource Protection Under SMP** configurable option is provided. Refer to flag definition " OS_PROTECTION_USE_MUTEX_LOCK" for further details. If you more than two cores or if you see serious performance issues then it is recommended to use Mutex Lock by setting **OS_PROTECTION_USE_MUTEX_LOCK** flag to **OS_TRUE** in **cross_os_usr.h** file. Spin lock is useful if protection is required for a short time. Spinlock wastes CPU if protection required is for longer periods or you have many more cpu cores.

Limitations:

In VxWorks there is a limitation to set affinity to a single core only. Hence in OS_Application_Init.c and OS_Create_Process.c, the affinity mask in the respective init_info structures should be passed accordingly.

SMP is not supported on the following OSs:

- µCOS
- Nucleus
- ThreadX
- MQX
- uITRON
- Android
- T-Kernel
- uITRON
- QNX
- Solaris
- NetBSD
- LynxOS
- FreeRTOS

OS Abstractor Target OS Specific Notes

Nucleus PLUS Target

The following is the compilations define that has to be set when building the Nucleus PLUS library in order for the OS Abstractor to perform correctly:

Table 2_21: Compilation Flag For Nucleus PLUS Target

Compilation Flag	Meaning
NU_DEBUG	Regardless of the target you build, the OS Abstractor library always requires this flag to be set in order to be able to access OS internal data structures. Without this flag, you will see a lot of compiler errors.

ThreadX Target

The ThreadX port for Win32 has a user defined memory ceiling which has a default value of 64K. If you run into issues with memory not being available, you will need to increase the memory limit. This define is called TX_WIN32_MEMORY_SIZE and is located in tx_port.h.

Precise/MQX Target

The following are the compilation defines that has to be set if you are using Precise/MQX as your target OS:

Table 2_22: Compilation Flag for Precise/MQX Target

Compilation Flag	Meaning
MQX_TASK_DESTRUCTION	Set this macro to zero to allow OS Abstractor to manage destruction of MQX kernel objects such as semaphores.
BSP_DEFAULT_MAX_MSGPOOLS	Set this macro to match the maximum number of message queues and pipes required by your application at a given time. For example, if your application would need a max of 10 message queues and 10 pipes, then this macro needs to be set to 20.

The MQX_TASK_DESTRUCTION macro is located in source\include\mqx_cnfg.h in your MQX installation. Set it to zero as shown below (or pass it to compiler via pre-processor setting in your project make files):

```
#ifndef MQX_TASK_DESTRUCTION
#define MQX_TASK_DESTRUCTION 0
#endif
```

The BSP_DEFAULT_MAX_MSGPOOLS macro is located in source\bsp\bspname\bspname.h in your MQX installation, where bspname is the name of your BSP. Set the required value as follows:

```
#define BSP_DEFAULT_MAX_MSGPOOLS (20L)
```

Linux Target

User Vs ROOT Login

OS Abstractor internally checks the user ID to see if the user is ROOT or not. If the user is ROOT, then it will automatically utilize the Linux real time policies and priorities. It is always recommended that OS Abstractor application be run under ROOT user login. In this mode:

- OS Abstractor task priorities, time slice, pre-emption modes and critical region protection features will work properly.
- OS Abstractor applications will have better performance and be more deterministic behavior since the Linux scheduler is prevented to alter the tasks priorities behind the scenes.
- Also, when you load other Linux applications (that uses the default SCHED_OTHER policies), they will not impact the performance of the OS Abstractor applications that are running under real-time priorities and policies.

Under non-ROOT user mode, the task scheduling is fully under the mercy of the Linux scheduler. In this mode, the OS Abstractor does not utilize any real-time priorities and/or policies. It will use the SCHED_OTHER policy and will ignore the application request to set and/or change scheduler parameters like priority and such. OS Abstractor applications will run under the non-ROOT mode, with restrictions to the following OS Abstractor APIs:

- OS_Create_Task: The function parameters *priority, time-slice* and OS_NO_PREEMPT flag options are ignored
- OS_Set_Task_Priority: This function will have no effect and will be ignored
- OS_Set_Task_Preemption: Changing the task pre-emption to OS_NO_PREEMPT has no effect and will be ignored
- OS_Protect: Will offer NO critical region data protection and will be ignored. If you need protection, then utilize OS Abstractor mutex features
- OS_Create_Driver: The OS Abstractor driver task will NOT be run at a higher priority level that the OS Abstractor application tasks.

  Though OS Abstractor applications may run under non-ROOT user mode, it is highly recommended that the real target applications be run under ROOT user mode.

System Resource Configuration

Linux has a limit on the sysv system resources. Typically, OS Abstractoris able to adjust these limits as required. But, if the CAP_SYS_RESOURCE capability is disabled, OS Abstractorwill not have the proper access privileges to do so. In this case, the values will need to be adjusted manually using an account with the proper capabilities enabled, or the kernel will need to be modified and rebuilt with the increased number of resources set as a default.

Time Resolution

The value of the system clock ticks is defined by OS_TIME_RESOLUTION, which is retrieved from the Linux system. Under Red Hat®/GNU® Linux, this is actually 100 (this means every tick equals to 10ms). However, the OS_TIME_TICK_PER_SEC could be different under other real-time or proprietary Linux distributions.

Also, make sure you modify OS_DEFAULT_TSLICE value to match with your application needs if necessary. By default, this value is set for the time slice to be 100ms. If the Linux Advanced

Real Time Feature is present (i.e the Linux kernel macro LINUX_ADV_REALTIME == 1), then OS Abstractor automatically takes advantage of this feature if present and uses the `sched_rr_set_interval()` function and sets the application required round-robin thread time-slice for the OS Abstractor thread. If this feature is not present, the time-slice value for round-robin scheduling will be whatever the kernel is configured to.

Memory Heap

OS Abstractor uses the system heap directly to provide the dynamic variable memory allocation. The Memory management for the variable memory is best left for the Linux kernel to be handled, so OS Abstractor only does boundary checks to ensure that the application does not allocate beyond the pool size. The maximum memory the application can get from these pools will depend on the memory availability of the system heap.

Priority Mapping Scheme

The OS Abstractor uses priorities 0~255 plus one more for exclusivity which results in a total of 257 priorities. If the Linux that you use provides less than 257 priority values, then OS Abstractor maps its priority in a simple window-mapping scheme where a window of OS Abstractor priorities gets mapped to each individual Linux priority. If the Linux that you use provides more than 257 priority values, then the OS Abstractor maps it priority one-on-one somewhere in the middle of the range of Linux priorities. Please modify the priority scheme as necessary if required by your application. If you want to minimize the interruption of the external native Linux applications then you would want the OS Abstractor priorities to map to the higher end of the Linux priority window.

OS Abstractor priority value of 257 is reserved internally by OS Abstractor to provide the necessary exclusivity among the OS Abstractor tasks when they request no preemption or task protection. The exclusivity and protections are not guaranteed if the external native Linux application runs at a higher priority.

It is recommended that the Linux kernel be configured to have a priority of 512, so that the OS Abstractor priorities will use the window range in the middle and as such would not interfere with some of core Linux components. If your Linux kernel is configured to have less than 257 priorities, the OS Abstractor will automatically configuring a windowing scheme, where multiple number of OS Abstractor priorities will map to a single Linux priority. Because of this, the reported priority value could be slightly different than what was used during the task creating process. If your application uses the pre-processor called OS_DEBUG_INFO, then all the priority values and calculations will be printed to the standard output device.

Memory and System Resource Cleanup

OS Abstractor uses shared memory to support multiple OS Abstractor and OS Changer application processes that are built with OS_INCLUDE_PROCESS mode set to OS_TRUE.

Single-process Application Exit

This will apply to application that does not use the OS_PROCESS feature. Each application needs to call OS_Application_Free to unregister and free OS Abstractor resources used by the application. Under circumstances where the application terminates abnormally, the applications need to install appropriate signal handler and call OS_Application_Free within them.

Multi-process Application Exit

This will be the case where the applications are built with OS_PROCESS feature set to OS_TRUE. When the first multi-process application starts, shared memory is created to accommodate all the shared system resources for all the multi-process application. When subsequent multi-process application gets loaded, they will register and OS Abstractor will create all the local resources (memory heap) necessary for the application. Application's can also spawn new applications using OS_Create_Process and will result the same as if a new application get's loaded. Each application needs to call OS_Application_Free to unregister and free OS Abstractor resources used by the application. Under circumstances where the application terminates abnormally, the applications need to install appropriate signal handler and call OS_Application_Free within them. When the last application calls OS_Application_Free, then OS Abstractor frees the resources used by the application and also deletes the shared memory region.

Manual Clean-up

If application terminates abnormally and for any reason and it was not possible to call OS_Application_Free, then it is recommended that you execute the provide **cleanup.pl** script manually before starting to load applications. Users can query the interprocess shared resources status by typing ipcs in the command line.

Multi-process Zombie Cleanup

There are circumstances where a multi-process application terminates abnormally and was not able to call OS_Application_Free. In this case, the shared memory region would be left with a zombie control block (i.e there is no native process associated with the OS Abstractor process control block). Whenever, a new multi-process application get's loaded, OS Abstractor automatically checks the shared memory region for zombie control blocks. If it finds any, it will take the following action:

Free and initialize all the control blocks that belong to the zombie process (this could even be the zombie process of the same application currently being loaded but was previously terminated abnormally).

Task's Stack Size

The stack size has to be greater than PTHREAD_STACK_MIN defined by Linux, otherwise, any OS Abstractor or OS Changer task creation will return success, but the actual task (pthread) will never get launched by the target OS. It is also safe to use a value greater than or equal to OS_MIN_STACK_SIZE defined in cross_os_def.h. OS Abstractor ensures that OS_STACK_SIZE_MIN is always greater that the minimum stack size requirement set by the underlying target OS.

Scheduling Policy of VxWorks threads

```
/*****************************************************************************/
/* Defines the scheduling policy used when creating VxWorks threads.        */
/*****************************************************************************/

#define OS_FIFO_POLICY                0
#define OS_RR_POLICY                  1
#define OS_VXWORKS_TASK_THREAD_POLICY   OS_FIFO_POLICY
```

Notes: If the Vxworks application is running tight and not allowing other programs to run, then set the vxworks thread policy to round robin in the file cross_os_usr.h. In this case, the threads will relinquish control after the default time slice (which is OS_MIN_TIME_SLICE defined in cross_os_usr.h). Having round robin real-time policy with a say a timeslice value of 10ms will result in preventing vxworks application dominating the CPU.

Windows Target

`OS_Relinquish_Task` API uses Window's sleep() to relinquish task control. However, the sleep() function does not relinquish control when stepping through code in the debugger, but behaves correctly when executed. This is a problem inherent in the OS itself.

If you have windows interface turned ON (i.e OS_INCLUDE_WINDOWS = OS_TRUE) along with other interface libraries in your project, make sure the project is build with process mode flag is turned ON (i.e INCLUDE_OS_PROCESS = OS_TRUE). If you build one interface library with process mode flag turned OFF and other interface libraries with process mode flag ON then segmentation fault will occur due to mismatch all libraries not being built with the current process feature.

LynxOS Target

Installing and Building the LynxOS Platform

Prerequisites:

To install and build LynxOS v7.0.0 requires the following packages:

- Installing Luminosity IDE using GUI Installer are provided in *the Luminosity v5.1.0 Installation Guide*
- Complete details for installing and uninstalling the Cross-Development Environments are provided in the corresponding *LynxOS-178 Installation Guide or LynxOS Installation Guide.*
- Complete details for installing and uninstalling the FLEXnet software and the procedure to obtain a license key are provided in the *License Management Software User's Guide*.
- Complete details for installing and uninstalling LOCI are provided in the *LOCI Release Notes*
- LynxOS 7 provides support for a variety of X86 and PowerPC target architectures. For details of the architectural components, refer LynxOS 7.0.0 user guide.

Adding Mapusoft Products to the LynxOS Platform

To add MapuSoft products to LynxOS 7.0 Platform: We need to start as follows:

- Ensure that AppCOE 1.5 to be installed on the Windows host machine.
- Ensure that the license server FLEXnet is installed on the Windows Host system.
- Run the lmgrd server after obtaining the license file on the command prompt:

```
c:\flexlm\v11.8\win32>lmgrd -c
c:\flexlm\v11.8\win32\license_file.dat
```

- Create the LynxOS kernel image(==kdi image) on the LynxOS cross development platform on Windows host machine with the respect to board support package(bsp) provided for target board. Type the following command on the cross development platform after configuring on the config.tbl file in the bsp provided:

`touch configure.tbl && make install && make netkdi && mv net.img file_name.kdi && ls -al file_name.kdi`, where file_name is the name of the kdi image.

- Boot the LynxOS kernel image on the bare target board through the PXE boot.
- Put the kernel image (==kdi image) on the TFTP/DHCP/PXE directory, rename as pxe.1.Similary put the boot loader file (pxe.0 file) from the (For example: C:\Lynx\Cygwin-1.7.33\usr\lynxos\7.0.0\x86\net) into the TFTP/DHCP/PXE directory.
- The TFTP/DHCP/PXE knows everything about your target PC such as mac address as well as under the same subnet. Once you power-on your target board/PC, it will start booting through PXE boot and finally on the target PC/board ,"LynxOS Version 7.0.0" title along with the copyright printed out.
- The PXE boot is done through the Realtek 8139 Ethernet card on the target PC/board. After boot-up on the target PC/board, put the Ethernet cable on the Intel PRO/1000 8254x slot. Ensure we should have two NIC card on the bare target board/PC.
- Now on the LynxOS, login as "root" with skipping the password. Now again we have to login in the "sysadm" to get the privilege. Type the following command to get the privilege: surole `sysadm` on the LynxOS target terminal along with password and confirm password as "mapusoft".
- Now with "`ifconfig`" command, you can able to see your external interface along with loopback interface.
- Ensure you extracted the LOCI file and kept in the *C:\Lynx\Cygwin-1.7.33\usr\lynxos\7.0.0\x86\usr* before making the kernel image. Now on the LynxOS target file system, you can find the lwsrvr on the LOCI directory. Type the following command: `PATH=$PATH:/usr/loci/bin` followed by `lwsrvr -D` to run the lwsrvr server.
- Now your loci server is running on the target board/PC. Ensure that you can able to ping the host PC from the target console through the network cable.
- From the luminosity IDE, go to register remote target registry and select network connection along with LOCI enabled. Set the target ip address and other settings, then validate for connection establishment between luminosity and LOCI on target pc/board. Once validation succeeded then the binary of the application program can be downloaded to run/debug on LynxOS target.

Configuring and building the cross_os_lynxos libraries.

- Ensure that AppCOE 1.5 is installed on your host PC.
- Open the AppCOE, go to the tools.
- Select the full library package.
- Select the LynxOS target.
- Select any interface, if required. Click "Next" to create the cross_os_LynxOS library package and store it in any destination folder. The destination folder will contain cross_os library, demo_cross_os, include files and docs as we have not selected any interfaces.
- Open the Luminosity IDE v 5.1.0.Go to File->New-> Lynx C project. In the project creation wizard, name as "cross_os_LynxOS", project type "Managed make static library.
- In the project code generator section, select the "empty project" and also uncheck the stub option.

- After next –next options, in the left side of the IDE, in the project explorer, the project (for example: cross_os_lynxos will be displayed.).
- Navigate the destination folder file system (where the library package is saved) and import the include and source files of cross_os into the luminosity IDE on the cross_os_lynxos target.
- In the properties of the cross_os_lynxos project on the luminosity IDE, Resource- linked Resources Set “ROOTDIR” as your current workspace.
- In the properties->C/C++ project->symbols, set the following settings: OS_HOST=OS_FALSE, OS_TARGET=OS_LYNXOS and OS_CPU_64BIT=OS_FALSE.
- In the include section of the properties, include the path of the include file as well as cross_os include file of the destination folder.
- Now in tool chain editor section, default settings should be made .So that we can able to build the binary through gcc compiler.
- Rest in all sections, default settings will come automatically.
- After the following settings are done, we can able to build the cross_os_lynxos library on the luminosity IDE. Now the library file is created successfully.

Configuring and building the Demo application.

- Similarly select the File-> New->Lynx C project on the luminosity IDE.
- In the project creation wizard, name as “demo_2”(suppose for example), project type “Managed Executable”.
- In the project code generator section, select the “empty project” and also uncheck the stub option.
- After next –next options, in the left side of the IDE, in the project explorer, the project (for example: demo_2 will be displayed.) same as you did in cross_os_lynxos.
- Navigate the destination folder file system (where the library package is saved) and import the include and source files of demo_cross_os into the luminosity IDE on the demo_2 target.
- In the properties of the demo_2 project on the luminosity IDE, Resource- linked Resources Set “ROOTDIR” as your current workspace.
- In the properties->C/C++ project->symbols, set the following settings: OS_HOST=OS_FALSE,OS_TARGET=OS_LYNXOS and OS_CPU_64BIT=OS_FALSE.
- In the include section of the properties, set the path of the include file as well as cross_os include file and demo_cross_os include files of the destination folder.
- Now in tool chain editor section, default settings should be made .So that we can able to build the binary through gcc compiler.
- Set the name of the library that is cross_os_lynxos that we made before and the path of the library(location where cross_os library file is build and created).
- Proper indexing should be done so that it can link properly.
- Rest in all sections, default settings will come automatically.
- After the following settings are done, we can able to build the demo_2 successfully on the luminosity IDE.
- Now select the binary entry in the demo_2 application, right click on the binary, then select Run- > Run As-> Lynx C/C++ in the context menu. By this the binary will be deployed to the target. Even the output will come on the right hand side of the luminosity target simulator. Binary that is being deployed on the lynxOS target(normally on the user directory that is for example“vl”).Now on lynxOS target go into the “vl “ directory from the root by the command : `cd /home/vl`. Then if the binary of demo_2 is located by its filename (demo_2), then type the command:. /filename(for example: `./demo_2`) to run on the target

Android Target

Installing and Building the Android Platform

Prerequisites:

To install and build Android requires the following packages:

- JDK 5.0 update 12 or higher. Java 6 will not work. – Download from http://java.sun.com
- Android 1.5 SDK – Download from http://developer.android.com/sdk/1.5_r3/index.html
- Android 1.5 NDK – Download from http://developer.android.com/sdk/ndk/1.5_r1/index.html

Refer to the Android website for instructions on how to properly install and configure the SDK and the NDK.

It is very important that JDK 6 is not used. JDK 6 will cause compiler errors. If you have both JDK's installed confirm that JDK 5.0 is the one that will be used by using the command:

```
$ which java
```

Adding Mapusoft Products to the Android Platform

To add Mapusoft products to Android Platform:

1. Add the Mapusoft project into the ~/android-ndk-1.5_r1/sources directory. This directory is referred to as <MAPUSOFT_ROOT>.
2. Run the setup.sh script located in <MAPUSOFT_ROOT>/cross_os_android. This creates symbolic links for the demo applications.

   The command used to build the applications is

```
$ make APP=<app_name>
```

For instance, to build the OS Abstractor demo the command would be

```
$ make APP=demo_cross_os
```

Running the Demos from the Android Emulator

To run the demos from Android Emulator:

1. Follow the steps documented on the Android developer site on how to create an AVD for the emulator.
2. Launch the emulator with the command:
   ```
   $ emulator -avd <avd_name>
   ```
3. Open another terminal and enter the command:
   ```
   $ adb logcat
   ```
   This will capture the log output from the emulator.
4. After the emulator launches click on the menu button to unlock the phone.
5. Click on the popup arrow on the screen.
6. The demos should be listed in the list of applications. Click on one to launch it. The demo output will be piped into the adb terminal window.

QNX Target

User Vs ROOT Login

OS Abstractor internally checks the user ID to see if the user is ROOT or not. If the user is ROOT, then it will automatically utilize the Linux real time policies and priorities. It is always recommended that OS Abstractor application be run under ROOT user login. In this mode:

- OS Abstractor task priorities, time slice, pre-emption modes and critical region protection features will work properly.
- OS Abstractor applications will have better performance and be more deterministic behavior since the Linux scheduler is prevented to alter the tasks priorities behind the scenes.
- Also, when you load other Linux applications (that uses the default SCHED_OTHER policies), they will not impact the performance of the OS Abstractor applications that are running under real-time priorities and policies.

Under non-ROOT user mode, the task scheduling is fully under the mercy of the Linux scheduler. In this mode, the OS Abstractor does not utilize any real-time priorities and/or policies. It will use the SCHED_OTHER policy and will ignore the application request to set and/or change scheduler parameters like priority and such. OS Abstractor applications will run under the non-ROOT mode, with restrictions to the following OS Abstractor APIs:

OS_Create_Task: The function parameters priority, time-slice and OS_NO_PREEMPT flag options are ignored

- OS_Set_Task_Priority: This function will have no effect and will be ignored
- OS_Set_Task_Preemption: Changing the task pre-emption to OS_NO_PREEMPT has no effect and will be ignored
- OS_Protect: Will offer NO critical region data protection and will be ignored. If you need protection, then utilize OS Abstractor mutex features
- OS_Create_Driver: The OS Abstractor driver task will NOT be run at a higher priority level that the OS Abstractor application tasks.

Though OS Abstractor applications may run under non-ROOT user mode, it is highly recommended that the real target applications be run under ROOT user mode.

Time Resolution

The value of the system clock ticks is defined by `OS_TIME_RESOLUTION`, which is retrieved from the Linux system. Under Red Hat®/GNU® Linux, this is actually 100 (this means every tick equals to 10ms). However, the `OS_TIME_TICK_PER_SEC` could be different under other real-time or proprietary Linux distributions.

Also, make sure you modify `OS_DEFAULT_TSLICE` value to match with your application needs if necessary. By default, this value is set for the time slice to be 100ms.

Memory Heap

OS Abstractor uses the system heap directly to provide the dynamic variable memory allocation. The Memory management for the variable memory is best left for the Linux kernel to be handled, so OS Abstractor only does boundary checks to ensure that the application does not allocate beyond the pool size. The maximum memory the application can get from these pools will depend on the memory availability of the system heap.

Priority Mapping Scheme

QNX native priority value of 255 will be reserved for OS Abstractor Exclusivity. The rest of the 255 QNX priorities will be mapped as follows:

0 to 253 OS Abstractor priorities -> 254 to 1 QNX priorities
254 and 255 OS Abstractor priorities -> 0 QNX priority
The OS Abstractor uses priorities 0~255 plus one more for exclusivity which results in a total of 257.

Memory and System Resource Cleanup

Please refer to the same section under target specific notes for Linux operating system.

Task's Stack Size

The stack size has to be greater than PTHREAD_STACK_MIN defined by Linux, otherwise, any OS Abstractor or OS Changer task creation will return success, but the actual task (pthread) will never get launched by the target OS. It is also safe to use a value greater than or equal to OS_STACK_SIZE_MIN defined in def.h. OS Abstractor ensures that OS_STACK_SIZE_MIN is always greater that the minimum stack size requirement set by the underlying target OS.

Dead Synchronization Object Monitor

Use OS_Monitor_Register function to register a process as a dead synchronization object monitor. A dead synchronization object situation can occur if a process is terminated while it owns a synchronization object such as a mutex or a pthread_spinlock. When this happens any other processes suspended on that object will never be able to acquire it. This situation can only occur if the synchronization object is shared between processes. For further information about OS_Monitor_Register function, refer to the OS Abstractor Interface Reference Manual. This feature is not supported in all the target OS.

VxWorks Target

Version Flags

The following is the compilation defines that has to be set when building the OS Abstractor library for VxWorks target OS:

Table 2_24: Version Flags for VxWorks Target

Compilation Flag	Meaning
OS_VERSION	Specify the VxWorks version. The value can be: **OS_VXWORKS_5X** – VxWorks 5.x or older **OS_VXWORKS_6X** – Versions 6.x or higher
OS_USER_MODE	Set this value to **OS_TRUE** if the OS Abstractor is required to run as a application module. Under OS_VXWORKS_5X, the OS_KERNEL_MODE flag is ignored. The library is built to run as application module. Under OS_VXWORKS_6X, you have the option to create the library for either as a kernel module or a user application as below: OS_USER_MODE = OS_TRUE for application module OS_USER_MODE =OS_FALSE for kernel module.
OS_KERNEL_MODE	Set this value to **OS_TRUE** if the OS Abstractor is required to run as a kernel module. Under OS_VXWORKS_5X, the OS_KERNEL_MODE flag is ignored. The library is built to run as a kernel module. Under OS_VXWORKS_6X, you have the option to create the library for either as a kernel module or a user application as below: OS_KERNEL_MODE = OS_TRUE for kernel module OS_KERNEL_MODE = OS_FALSE for user application.
OS_VXWORKS_TARGET	Select your appropriate Target platform. The value can be: OS_VXWORKS_PPC OS_VXWORKS_PPC_604 OS_VXWORKS_X86 OS_VXWORKS_ARM OS_VXWORKS_M68K OS_VXWORKS_MCORE OS_VXWORKS_MIPS OS_VXWORKS_SH OS_VXWORKS_SIMLINUX OS_VXWORKS_SIMNT OS_VXWORKS_SIMSOLARIS OS_VXWORKS_SPARC

Unsupported OS Abstractor APIs

The following OS Abstractor APIs are not supported as shown below:

Table 2_25: Unsupported OS Abstractor APIs for VxWorks Target

Compilation Flag	Unsupported APIs
OS_VERSION = OS_VXWORKS_5X	OS_Delete_Partion_Pool OS_Delete_Memory_Pool OS_Get_Semaphore_Count
OS_VERSION = OS_VXWORKS_6X and OS_KERNEL_MODE = OS_TRUE	OS_Set_Clock_Ticks
OS_VERSION = OS_VXWORKS_6X and OS_KERNEL_MODE = OS_FALSE	OS_Get_Semaphore_Count

Application Initialization

Once you have configured the OS Abstractor (refer to chapter OS Abstractor Configuration), now you are ready to create a sample demo application.

Application needs to initialize the OS Abstractor library by calling the OS_Application_Init() function prior to using any of the OS Abstractor function calls. Please refer to subsequent pages for more info on the usage and definition of OS_Application_Init function.

The next step would be is to create the first task and then within the new task context, application needs to call other initializations functions if required. For example, to use the POSIX Interface component, application need to call OS_Posix_Init() function within an OS Abstractor task context prior to using the POSIX APIs. The OS_Posix_Init() function initializes the POSIX library and makes a function call to px_main() function pointer that is passed along within OS_Posix_Init() call. Please note that the px_main() function is similar to the main() function that is typically found in posix code. Please refer to the example initialization code shown at the end of this section.

If the application also uses OS Changer components, then the appropriate OS Changer library initialization calls need to be made in addition to POSIX initialization. Please refer to the appropriate Interface reference manual for more details.

Please refer to the init.c module provided with the sample demo application for the specific OS, tools and target for OS Abstractor initialization and on starting the application.

If you need to re-configure your board differently or would like to use a custom board, or would like to re-configure the OS directly, then refer to the appropriate documentations provided by the OS vendor.

Example: OS Abstractor for Windows Initialization

```
int main(int   argc,
         LPSTR argv[])
{
    OS_Main();

    return (OS_SUCCESS);
} /* main */

#if (OS_HOST == OS_TRUE)
/* The below defines are the system settings used by the OS_Application_Init()
function. Use these to modify the settings when running on the host.  A value of -1
for any of these will use the default values located in cross_os_usr.h.
   When you optimize for the target side code, the wizard will create a custom
cross_os_usr.h  using the settings you specify at that time so these defines will no
longer be necessary. */
#define HOST_TASK_POOLING                    OS_FALSE  /* to use task pooling, set
this to OS_TRUE, and make sure
                                                          add tasks to pool using
OS_Add_To_Pool apis */

Runtime Memory Allocations

OS Abstractor Interface

Some of the allocations for this product will be dependent on the native OS. Some of these may be generic among all products. The thread stacks should come from the process heap. This is only being done on the OS Abstractor for QNX product at the moment.

- Message in int_os_send_to_pipe
- Device name in os_creat
- Partitions in os_create_partition_pool
- Device name in os_device_add
- File structures in os_init_io
- Driver structures in os_init_io
- Device header for null device in os_init_io
- Device name for the null device in os_init_io
- Device name in os_open
- Environment structure in os_put_environment
- Environment variable in os_put_environment
- Memory for profiler messages if profiler feature is turned ON
- Thread stack (only under QNX)

POSIX Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool:

- Pthread key lists and values
- Stack item in pthread_cleanup_push
- Sem_t structures created by sem_open.
- Timer_t structures created by timer_create.
- mqueue_t structures created by mq_open.
- Message in mq_receive. This is deallocated before leaving the function call.
- Message in mq_send. This is deallocated before leaving the function call.
- Message in mq_timedreceive. This is deallocated before leaving the function call.
- Message in mq_timedsend. This is deallocated before leaving the function call.

All of the following are specific to the TKernel OS and use the SMalloc api call. These will not be accounted for in the process memory pool:

- Parameter list for execve
- INT_PX_FIFO_DATA structure in fopen

All of the following are specific to the TKernel OS and use os_malloc_external API call. These will not be accounted for in the process memory pool.

- Buffer for getline
- Globlink structure in int_os_glob_in_dir
- Globlink name in int_os_glob_in_dir
- Directory in int_o_prepend_dir

micro-ITRON Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Message in snd_dtq. This is deallocated before leaving the function call.
- Message in psnd_dtq. This is deallocated before leaving the function call.
- Message in tsnd_dtq. This is deallocated before leaving the function call.
- Message in fsnd_dtq. This is deallocated before leaving the function call.
- Message in rcv_dtq. This is deallocated before leaving the function call.
- Message in prcv_dtq. This is deallocated before leaving the function call.
- Message in trcv_dtq. This is deallocated before leaving the function call.
- Message in snd_mbf. This is deallocated before leaving the function call.
- Message in psnd_mbf. This is deallocated before leaving the function call.
- Message in tsnd_mbf. This is deallocated before leaving the function call.
- Message in rcv_mbf. This is deallocated before leaving the function call.
- Message in prcv_mbf. This is deallocated before leaving the function call.

- Message in trcv_mbf. This is deallocated before leaving the function call.

VxWorks Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Wdcreate allocates memory for an OS_TIMER control block .
- Message in msgqsend. This is deallocated before leaving the function call.
- Message in msgqreceive. This is deallocated before leaving the function call

pSOS Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Rn_getseg will allocate from the System_Memory if a pool is not specified.
- Message in q_vsend. This is deallocated before leaving the function call.
- Message in q_vrecieve. This is deallocated before leaving the function call.
- Message in q_vurgent. This is deallocated before leaving the function call.

All of the following allocations use malloc. Depending on the setting of OS_MAP_ANSI_MEM these may or may not be accounted for in the process memory pool.

- IOPARMS structure in de_close
- IOPARMS structure in de_cntrl
- IOPARMS structure in de_init
- IOPARMS structure in de_open
- IOPARMS structure in de_read

Nucleus Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Message in nu_receive_from_pipe. This is deallocated before leaving the function call
- Message in nu_receive_from_queue. This is deallocated before leaving the function call
- Message in nu_send_to_front_of_pipe. This is deallocated before leaving the function call
- Message in nu_send_to_front_of_queue. This is deallocated before leaving the function call
- Message in nu_send_to_pipe. This is deallocated before leaving the function call
- Message in nu_send_to_queue. This is deallocated before leaving the function call

ThreadX Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Message in tx_queue_receive. This is deallocated before leaving the function call
- Message in tx_queue_send. This is deallocated before leaving the function call
- Message in tx_queue_front_send. This is deallocated before leaving the function call

FreeRTOS Interface

All of the following allocations use OS_Allocate_Memory using the System_Memory pool. Thus, all these allocations come from the calling processes memory pool.

- Message in xqueuereceive. This is deallocated before leaving the function call
- Message in xqueuesend. This is deallocated before leaving the function call
- Message in xqueuereset. This is deallocated before leaving the function call
- Message in xqueuesendtoback. This is deallocated before leaving the function call
- Message in xqueuesendtofront. This is deallocated before leaving the function call

OS Abstractor Process Feature

An OS Abstractor process or an application ("process") is an individual module that contains one or more tasks and other resources. A process can be looked as a container that provides encapsulation from other process. The OS Abstractor processes only have a peer-to-peer relationship (and not a parent/child relationship).

An OS Abstractor process comes into existence in two different ways. Application registers a new OS Abstractor process when it calls OS_Application_Init function. Application also launches a new process when it calls the OS_Create_Process function. In the later case, the newly launched process does not automatically inherit the open handles and such; however they can access the resources belonging to the other process if they are created with "system" scope.

Under process-based operating system like Linux, this will be an actual process with virtual memory addressing. As such the level of protection across individual application will be dependent on the underlying target OS itself.

Under non-process-based operating system like Nucleus PLUS, a process will be a specialized task (similar to a main() thread) owning other tasks and resources in a single memory model based addressing. The resources are protected via OS Abstractor software. This protection offered by OS Abstractor is software protection only and not to be confused with MMU hardware protection in this case.

OS Abstractor automatically tracks all the resources (tasks, threads, semaphores, etc.) and associates them with the process that created them. All the memory requirements come from its own process dedicated memory pool called "process system pool". Upon deletion of the process, all these resources will automatically become freed.

Depending on whether the resource needs to be shared across other processes, they can be created with a scope of either OS_SCOPE_SYSTEM or OS_SCOPE_PROCESS. The resources with system scope can be accessible or usable by the other processes. However, the process that creates them can only do deletion of these resources with system scope.

A new process will be created as a "new entity" and not a copy of the original. As such, none of the resources that are open becomes immediately available to the newly created process. The new created process can use the resources which were created with system scope by first retrieving their ID through their name. For this purpose, the application should create the resources with unique names. OS Abstractor will all resource creation with duplicate names, however the function that returns the resource ID from name will provide the ID of only the first entry.

Direct access to any OS Abstractor resource control blocks are prohibited by the application. In other words, the resource Ids does not directly point to the addresses of the control blocks.

Simple (single-process) Versus Complex (multiple-process) Applications

An OS Abstractor application can be simple (i.e. single-process application) or complex (multi-process application). Complex and large applications will greatly benefit in using the OS_INCLUDE_PROCESS feature support offered by OS Abstractor.

Table 2_26: Simple (single-process) Versus Complex (multiple-process) Applications

OS_INCLUDE_PROCESS = OS_FALSE (Simple OR Single-process Application)	OS_INCLUDE_PROCESS = OS_TRUE (Complex OR multi-process Application)
OS Abstractor applications are independent from each other and are complied and linked into a separate executables. There is no need for the OS Abstractor and/or OS Changer APIs to work across processes.	OS Abstractor applications can share the OS Abstractor resources (as long as they are created with system scope) between them even though they may be complied and linked separately. The OS Abstractor and/or OS Changer APIs works across processes.
Many independent or even clones of OS Abstractor single-process applications can be hosted on the OS platform.	In addition to independent single-process applications, the current release of OS Abstractor allows to host one multi-process application.
OS Abstractor applications do NOT spawn new processes via the OS_Create_Process function. In fact, any APIs with the name “process” in them are not available for a single-process application.	OS Abstractor applications can spawn new processes via the OS_Create_Process function.
Each application uses its own user configuration parameters set in the cross_os_usr.h file.	Each application has to have the same set of shared resources defined in the cross_os_usr.h (e.g. max number of tasks/threads across all multi-process applications). When the first multi-process application gets loaded, the OS Abstractor uses the values defined in cross_os_usr.h or the over-ride values passed along its call to OS_Application_Init function to create all the shared system resources. When subsequent multi-process application gets loaded, OS Abstractor ignores the values defined in the cross_os_usr.h or the values passed in the OS_Application_Init call. Please note that the shared resources are only gets created during the load time of the first application and they gets deleted when the last multi-process application exits.
OS Abstractor creates all the resource control blocks within the process memory individually for each application.	OS Abstractor creates all the resource control blocks in shared memory during the first OS_Application_Init function call. In other words, when the first application gets loaded, it will initialize the OS Abstractor library. After this, every subsequent OS_Application_Init call

	will register and adds the application as a new OS Abstractor process and also creates the memory pool for the requested heap memory. An application can delete or free or re-start itself with a call to OS_Application_Free. An application can delete or re-start another application via OS_Delete_Process. Also, it is up to the application to provide the necessary synchronization during loading individual applications so that the complex application will start to run only in the preferred sequence.

Memory Usage

The memory usage depends on whether your application is built in single process mode (i.e OS_INCLUDE_PROCESS set to false) or multi-processes mode (i.e OS_INCLUDE_PROCESS set to true).

The memory usage also depends on whether the target OS supports single memory model or a virtual memory model. Operating systems such as LynxOS, Linux, Windows XP, etc. are based on virtual memory model where each application are protected from each other and run under their own virtual memory address space. Operating systems like Nucleus PLUS, ThreadX, MQX, etc. are based on single memory model where each application shares the same address space and there is no protection from each other.

In general, OS Abstractor applications require memory to store the system configuration and also to meet the application heap memory needs.

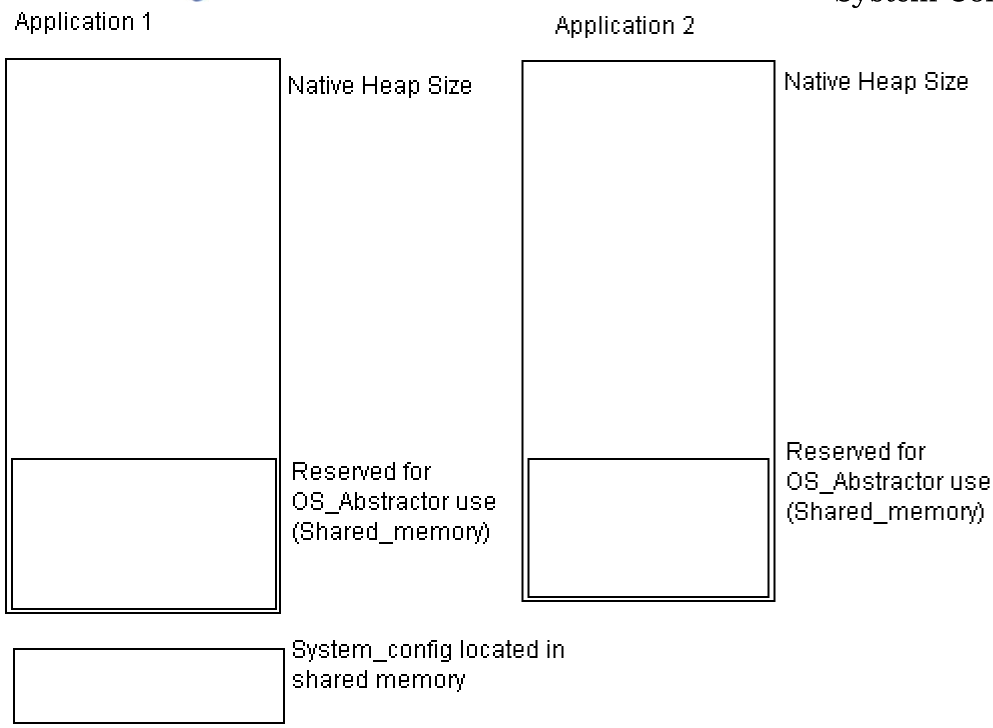
Memory Usage under Virtual memory model based OS

Multi-process Application

System_Config: The system config structure will be allocated from shared memory. The size will be returned to the user for informational use via the OS_SYSTEM_OVERHEAD macro.

OS_Application_Init: the memory value passed into this API by memory_pool_size will be the heap size for this particular process. In this type of system, it is possible to have multiple applications, all of which will call this API. This API will create an OS Abstractor dynamic memory pool the size of the heap. The global variable System_Memory will be set to the id of this pool.
OS_Create_Process: The memory value passed into this API by process_heap_size will be the heap size for this particular process. This API will create an OS Abstractor dynamic memory pool the size of the heap. The global variable System_Memory will be set to the id of this pool.

System_Memory: This will be set to the pool id of the process memory pool.

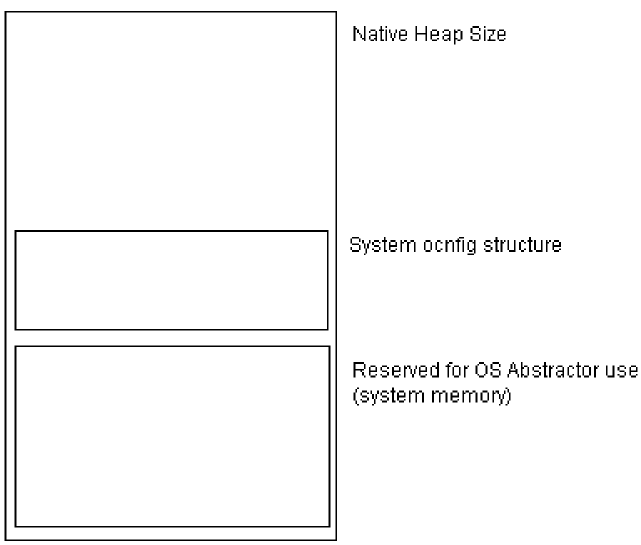


Single-process Application

System_Config: The system config structure will be allocated from the process heap. The size will be returned to the user for informational use only by calling OS_System_Overhead();

OS_Application_Init: the memory value passed into this API by memory_pool_size will be the amount of memory available to the system. This API will create an OS Abstractor dynamic memory pool this size. The memory for System_Config does not come from this pool. So the total memory requirements will be OS_SYSTEM_OVERHEAD + memory_pool_size.

System_Memory: This will be set to 0. Since there are no processes, the first pool will always be the system memory pool.



Native process heap size: We are not adjusting the native process heap size, so it could be possible that there is an inconsistency between the amount of memory reserved by OS Abstractor and the amount of memory reserved for the actual heap of the native process.
There is no upper bounds limit to the system wide memory use while in process mode. We will create processes without regard to the actual size of the physical memory.

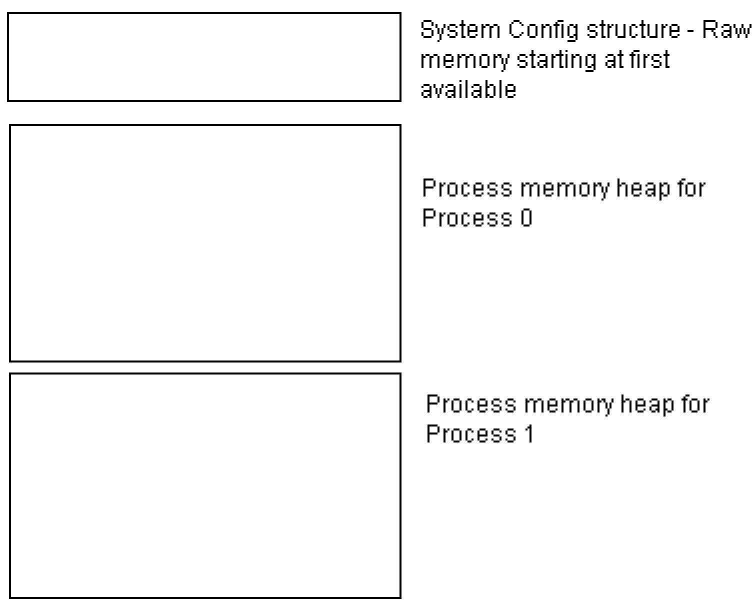
Memory Usage under Single memory model based OS

Multi-process Application

System_Config: The first available memory will be set in the OS_APP_INFO structure and will be adjusted the size of the system_config structure.

OS_Application_Init: The memory value passed into this API by memory_pool_size will be the heap size for this particular process. This API can only be called once since it is not possible to have multiple applications natively. This API will create an OS Abstractor dynamic memory pool the size of the heap.

OS_Create_Process: The memory value passed into this API by process_heap_size will be the heap size for this particular process. This API will create an OS Abstractor dynamic memory pool the size of the heap.
System_Memory: This will always be set to 0. When we get a pool id of 0 in any of the allocation APIs we will know to allocate from the current process memory pool. This means that the dynamic memory pool control block at index 0 is not to be used.

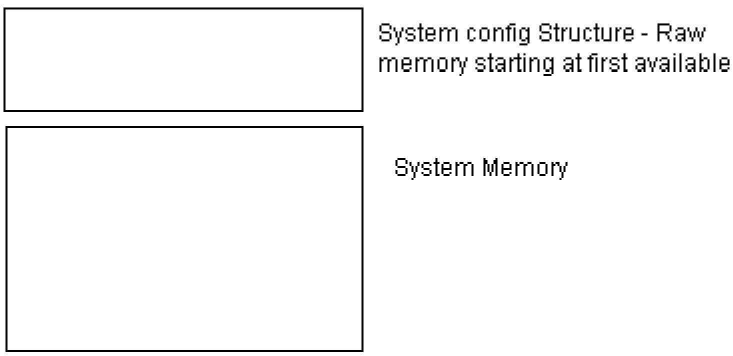


Single-process Application

System_Config: The first available memory will be set in the OS_APP_INFO structure and will be adjusted the size of the system_config structure.

OS_Application_Init: the memory value passed into this API by memory_pool_size will be the amount of memory available to the system. This API will create an OS Abstractor dynamic memory pool this size. The memory for System_Config does not come from this pool. So the total memory requirements will be OS_SYSTEM_OVERHEAD + memory_pool_size.

System_Memory: This will always be set to 0. Since we are not in process mode, there should not be any other OS Abstractor memory pools created.



There is no upper bounds limit to the system wide memory use while in process mode. Also, it cannot be guaranteed that there will be enough memory to create all the processes of the application since there is no total memory being reserved.

Revision History

Document Title: System Configuration Guide

Release Number: 1.8.1

Release	Revision	Orig. of Change	Description of Change
1.3.5	0.1	VV	• New document • Updated UITRON with micro-ITRON • Added revision history • Renamed Getting started to Programmers Guide • Changed the Programmers Guide description on page 8
1.3.6	0.1	VV	• Modified the Release number • Added the SMP Flag information • Added Android Specific notes • Added Ada System Configuration
1.3.7	0.1	VV	• Modified the Release number
1.3.8	0.1	VV	• Modified the Release number
1.3.9	0.1	VV	• Added the Threadx Interface • Added the Threadx Target • Added SMP Flag Limitation
1.3.9.1	0.1	VV	• Modified the Release number
1.3.9.2	0.1	VV	• Modified the Release number
1.4	0.1	VV	• Modified the Release number • Added the support of new apis in vxworks. • Added the support of process mode.
1.4.1	0.1	VV	• Modified the Release number
1.5	0.1	VV	• Updated FreeRTOS Target • Integrated µC/OS Interface • Integrated FreeRTOS Interface • Modified the Release number
1.6	0.1	VV	• Ada new release (Adacgen 4.041) • Integrated Complex Function in Ada-C/C++ Changer Product
1.7	0.1	VV	• Integrated RTLinux Interface
1.8.0	0.1	VV	• Bug fixes done on the previous release. • AppCOE has been updated to Eclipse IDE and Installed Features version Mars.2 (4.5.2) for all operating systems. • The Java Runtime Environment (JRE) has been updated to version 1.8 for all operating systems.
1.8.1	0.1	VV	• Bugs from the previous release resolved.

			• A new project type of "AppCOE" is added for code generation on Windows and Linux targets. • Installer replaced with a new, more advanced, installer which provides better usability, performance, and features.
